1 TITLE

2 Al/Cu/Mg/Ag alloy with Si, semi-finished product from such an
3 alloy as well as method for the production of such a semi-
4 finished product

5

6 CROSS REFERENCE APPLICATIONS

7 This application is a national phase application
8 claiming priority from PCT application no. PCT/EP2002/07193
9 filed on 29 June 2002.

10

11 FIELD OF INVENTION

12 Subject matter of the invention is an Al/Cu/Mg/Mn alloy
13 for the production of semi-finished products with high static
14 and dynamic strength properties. The invention further
15 relates to semi-finished products manufactured from such an
16 alloy with high static and dynamic strength properties as
17 well as to a method for the production of such a semi-
18 finished product.

19

20 BACKGROUND OF THE INVENTION

21 Aluminum alloys having a high static and dynamic bearing
22 capacity include the alloys AA 2014 and AA 2214. Drop-
23 forged parts for wheel and brake systems of airplanes are
24 manufactured from these Al alloys in the artificially aged
25 state. The semi-finished products produced from the alloy
26 intrinsically have the listed strength properties of the
27 alloys, especially at lower temperatures. However, at
28 temperatures of more than 100° C these properties decrease
29 more rapidly than is the case with alloys of the group AA
30 2618.

1 Semi-finished products of the alloys of group AA 2618
2 have better high-temperature stability and are utilized for a
3 variety of uses such as compressor impellers for rechargeable
4 diesel engines or for rotors of ultracentrifuges. However,
5 at temperatures below 100°C, the aluminum alloys of the group
6 AA 2014 and AA 2214 have greater bearing capacity.

7 In the wheel brake system of airplanes considerable heat
8 is generated during the braking process. This leads to
9 temperature increases even in the wheels, which typically are
10 fabricated of an AA 2014 or AA 2214 alloy. These can cause
11 early overageing of this alloy and lead to a severe
12 limitation of the service life of the structural part.

13 In compressor impellers the transition to titanium
14 alloys has been made to give the compressor impellers the
15 necessary static and dynamic strength properties even at
16 increased temperatures. However, employing titanium is
17 expensive is therefore not suitable for the production of
18 airplane wheels. Furthermore, titanium is less well suited
19 as a material for wheels due to its limited thermal
20 conductivity, .

21 The problematic described above is not new. Therefore,
22 for many years there has been the wish for an Al alloy, which
23 combines the high strength properties of the alloys AA 2014
24 or AA 2214 at ambient temperature and the thermal stability
25 of the alloys AA 2618 or 2618 A.

26 **SUMMARY OF THE INVENTION**

27 The invention therefore addresses the problem of
28 providing such an alloy, a semi-finished product produced of
29 such an alloy with high static and dynamic bearing capacity,
30 high thermal stability, high fracture toughness and high

1 creep resistance as well as a method for the production of
2 such semi-finished products.

3

4 Other aspects of this invention will appear from the
5 following description and appended claims, reference being
6 made to the accompanying drawings forming a part of this
7 specification wherein like reference characters designate
8 corresponding parts in the several views.

9 This problem is solved according to the invention with
10 an alloy that has the following composition:

11 0.3 - 0.7 wt. % silicon (Si)
12 maximally 0.15 wt. % iron (Fe)
13 3.5 - 4.5 wt. % copper (Cu)
14 0.1 - 0.5 wt. % manganese (Mn)
15 0.3 - 0.8 wt. % magnesium (Mg)
16 0.05 - 0.15 wt. % titanium (Ti)
17 0.1 - 0.25 wt. % zirconium (Zr)
18 0.3 - 0.7 wt. % silver (Ag)
19 maximally 0.05 wt. % other, individually
20 maximally 0.15 wt. % other, total
21 remaining wt. % aluminum (Al).

22

23 Compared to the prior known alloys AA 2014 and AA 2214,
24 the claimed alloy has higher static and dynamic thermal
25 stability and improved creep resistance while also having
26 very good mechanical fracturing properties. These properties
27 are attained in particular at a copper-magnesium ratio
28 between 5 and 9.5, in particular at a ratio between 6.3 and
29 9.3. The copper content is preferably between 3.8 and 4.2
30 wt. % and the magnesium content between 0.45 and 0.6 wt. %.
31 The copper content is markedly below the maximum solubility

1 for copper in the presence of the claimed magnesium content.
2 As a consequence, the fraction of insoluble copper-containing
3 phases is very low, also taking into consideration the
4 remaining alloy and companion elements. Thereby an
5 improvement is obtained with respect to the dynamic
6 properties and the fracture toughness of the semi-finished
7 products manufactured from such an alloy.

8 In contrast to the known AA alloys 2014 and 2219, a
9 portion of the claimed alloy is silver with contents between
10 0.3 and 0.7 wt. %, preferably 0.45 and 0.6 wt. %. In the
11 interaction with silicon (0.3 - 0.7 wt. %, preferably 0.4 -
12 0.6 wt. %) the hardening takes place via the same mechanisms
13 as in silver-free Al/Cu/Mg alloys. However, it has been
14 found that with lower silicon contents, the course of
15 precipitation is different due to the addition of silver.

16 While the semi-finished products manufactured from such
17 an alloy have good high-temperature stability and creep
18 resistances under cooler conditions, they do not meet the
19 desired requirements. Only silicon contents above 0.3 wt. %
20 suppress the otherwise typical change of the precipitation
21 behavior of Al/Cu/Mg/Ag alloys, such that unexpectedly higher
22 strength values can be attained without having to give up the
23 high-temperature stability and the creep resistance with the
24 Cu and Mg contents according to the invention.

25 The manganese content of the claimed alloy is 0.1 to 0.5
26 wt. %, preferably 0.2 - 0.4 wt. %. In the case of alloys
27 with higher manganese contents undesirable precipitation
28 processes were found with long-term high-temperature stress,
29 which led to a decrease of strength. For this reason the
30 manganese content is limited to 0.4 wt. %. However,

1 manganese is fundamentally required as an alloy component for
2 the control of the grain structure.

3 To balance the reducing effect of manganese with respect
4 to the grain structure control, the alloy contains zirconium
5 between 0.10 - 0.25 wt. %, preferably 0.14 - 0.20 wt. %. The
6 precipitating zirconium aluminides, as a rule, are developed
7 even more finely dispersed than manganese aluminides.
8 Moreover, it was found that the zirconium aluminides
9 contribute to the thermal stability of the alloy.

10 For grain sizing 0.05 - 0.15 wt. %, preferably 0.10 -
11 0.15 wt. % of titanium is added. The titanium is usefully
12 added in the form of an Al/5Ti/1B prealloy, whereby boron is
13 automatically included in the alloy. Finely dispersed,
14 insoluble titanium diborides are formed therefrom. These
15 contribute to the thermal stability of the alloy.

16 The alloy can comprise maximally 0.15 % iron, preferably
17 0.10%, as an unavoidable contamination.

18

19 BRIEF DESCRIPTION OF THE DRAWINGS

20

21 Fig. 1 is a graph showing the 0.2% yield strength and the
22 tensile strength of the alloy according to the
23 invention in state T6 in comparison to prior known
24 alloys, as a function of the test temperature.

25

26 Fig. 2 is a graph showing the long-time stress to rupture
27 strength of the alloy according to the invention in
28 state T6 in comparison to known alloys.

29

30 Fig. 3 is a graph showing the 0.2% yield strength and the
31 tensile strength of airplane wheels manufactured from

1 the alloy according to the invention in comparison to
2 such manufactured from known alloys.

3
4 Figs. 4a and 4b are graphs showing the fatigue strength of
5 the alloy according to the invention in comparison to
6 a known alloy in state T6 at ambient temperature and
7 at a temperature of 200° C.

8
9 Before explaining the disclosed embodiment of the
10 present invention in detail, it is to be understood that the
11 invention is not limited in its application to the details of
12 the particular arrangement shown, since the invention is
13 capable of other embodiments. Also, the terminology used
14 herein is for the purpose of description and not of
15 limitation.

16 17 **DETAILED DESCRIPTION OF THE INVENTION**

18 Table 1 reproduced below shows the chemical composition
19 of four alloys (B, C, D, E) according to the invention as
20 well as the composition of the alloys AA 2214 and AA 2618
21 examined as a comparison (data in wt. % (n.d.: not
22 determined)

3

4 From these alloys semi-finished products were manufactured
5 following the method steps listed below:

6 a) casting of an ingot from an alloy,

7 b) homogenizing the cast ingot at a temperature, which is as
8 close under the incipient melting temperature of the alloy as
9 is possible, for a length of time adequate to attain

10 maximally uniform distribution of the alloy elements in the
11 cast structure,

12 c) hot working of the homogenized ingot by forging at a
13 block temperature of approximately 420°C,

14 d) solution treatment of the semi-finished product worked by
15 forging at temperatures sufficiently high to bring the alloy
16 elements necessary for the hardening into solution such that
17 they are uniformly distributed in the structure, with the
18 solution treatment taking place in a temperature range of
19 505°C over a time period of 3 hours,

1 e) quenching of the solution-treated semi-finished product
2 in water at ambient temperature,
3 f) cold working of the quenched semi-finished products by
4 cold upsetting by 1 to 2%, and
5 g) artificial ageing of the quenched semi-finished product
6 at a temperature of 170°C over time period of 20 to 25 hours.
7 The open-die forged pieces produced in this manner were
8 subsequently tested for their properties in the artificially
9 aged state T6.

7 ST= short transverse direction: parallel to the thickness direction

8

9 The improved strengths of the alloy according to the
10 invention (for example alloy E) is clearly evident in Tables
11 2 and 3. For example, while the prior known alloy AA 2214
12 shows good strength values at ambient temperature, it does
13 not at higher temperatures. Moreover, the creep resistance
14 and the fracture toughness are markedly better at ambient
15 temperature and at higher temperatures in the claimed alloy
16 compared to the prior known alloys. This comparison makes
17 clear that the tested prior known alloys have good properties
18 only with respect to a single strength parameter. In no case
19 do the prior alloys have good properties in all relevant

1 strength values at ambient temperature as well as at
 2 increased temperatures. Just as is the case with the fatigue
 3 properties, the creep resistance of this prior known alloy is
 4 not satisfactory. Very good properties over all tested
 5 strength parameters could only be determined in the case of
 6 the alloy according to the invention.

7 Figure 1 also makes graphically clear the better
 8 strength properties of the alloy (alloy E) according to the
 9 invention compared to the known alloys (AA 2214 as well as AA
 10 2618). The results showed unexpectedly that the strength
 11 values of alloy E are better even at temperatures below 100°C
 12 than those of the known alloy AA 2214, which is known for its
 13 especially high strength values in this temperature range.

14 Additionally, the creep resistance of the semi-finished
 15 products was tested. Table 4 shown below provides the test
 16 results (LMP: Larson Miller parameter) in summary:

17

18 **Table 4:**

Alloy											
E				AA 2214				AA 2618			
T_{test} (°C)	σ_{test} (MPa)	t_{fracture} (h)	LMP (-)	T_{test} (°C)	σ_{test} (MPa)	t_{fracture} (h)	LMP (-)	T_{test} (°C)	σ_{test} (MPa)	t_{fracture} (h)	LMP (-)
180	185	2513	10.60	205	200	30	10.27	205	183	10	10.04
	167	4762	10.82		190	50	10.38		179	50	10.38
					181	100	10.52		175	100	10.52
					130	500	10.85		163	500	10.85
					100	800	10.95		159	1000	11.00

19

20 Plotted graphically, the markedly better long-time stress to
 21 rupture strength of the alloy in the T6 state in comparison

1 to the known alloys AA 2214 and AA 2618 in the T6 state is
2 apparent. This is shown in Figure 2 as time-compensated
3 temperature representation. The especially good creep
4 resistance of the alloy according to the invention could not
5 be foreseen making this result surprising.

6 Within the scope of testing the method steps for the
7 production of these semi-finished products, it was found that
8 comparable material properties of the produced semi-finished
9 products can be attained if the step of hot working is
10 carried out at a block temperature between 320°C to 460°C.
11 The hot working can be either forging or rolling. The step
12 of quenching of the solution treated semi-finished product
13 can take place in a temperature range between ambient
14 temperature and 100°C (boiling) in water. It is also
15 possible to utilize a water-glycol mixture for the quenching,
16 the temperature of which- should not exceed 50°C.

17 A cold working step of a drawing out by 1% to 5% can be
18 carried out in the case of extruded or rolled products for
19 the purpose of reducing the intrinsic stresses due to the
20 quenching instead of the previously described step of cold
21 working through cold upsetting during forging. The step of
22 artificial ageing can be carried out over a time period of 5
23 to 35 hours, preferably between 10 and 25 hours, in a
24 temperature window between 170°C and 210 °C.

25 During further tests strand-cast ingots were produced as
26 described above and airplane wheels manufactured by drop
27 forging in the preforged die and finish forge die at a
28 temperature of 410 to 430°C. These wheels were subsequently
29 solution treated at 505°C, quenched in a mixture of water and
30 glycol of ambient temperature and thermally age-hardened at
31 170°C for 20 hours. These were compared to mass-produced

1 airplane wheels of the alloy AA 2214. Samples were taken
2 from the wheels produced of the claimed alloy and of the
3 conventional alloy at sites distributed over the
4 circumference, and tested for their tensile strength. The
5 results are shown in Figure 3. It can clearly be seen that
6 the alloy E according to the invention yields better values
7 compared to the known alloy AA 2214.

8 Fatigue tests in comparable samples of the two cited
9 alloys also show that the wheels produced from the claimed
10 alloy attain markedly better values than the wheels produced
11 from the alloy AA 2214. This applies to the fatigue tests
12 carried out at ambient temperature (cf. Figure 4a) as well as
13 to the fatigue tests carried out at a test temperature of
14 200°C (cf. Figure 4b).

15 The description of the claimed invention makes clear
16 that surprisingly the claimed alloys have not only high
17 dynamic and static strength values, but that they have an
18 especially good high-temperature stability, fracture
19 toughness and creep resistance. This alloy is therefore
20 particularly suitable for the production of semi-finished
21 products, which must meet precisely these requirements, such
22 as airplane wheels or compressors.

23 Although the present invention has been described with
24 reference to the disclosed embodiments, numerous
25 modifications and variations can be made and still the result
26 will come within the scope of the invention. No limitation
27 with respect to the specific embodiments disclosed herein is
28 intended or should be inferred. Each apparatus embodiment
29 described herein has numerous equivalents.

30
